

YOLO26 vs DEIMv2

A · Accuracy vs capacity — both at 640 px

B · Accuracy vs measured latency

Panel B asymmetry is a result, not an omission: four DEIMv2 variants (the DINOv3 line — s, m, l, x) convert to Core ML without error and then produce boxes 213–277 px wrong, so no latency is reported for them; atto/femto/pico sit below the capacity floor and were never exported.
